What is a microfilm reel? Microfilm is a roll or spool of film with sequential frames of images. These film reels look similar to rolls of movie films. Microfilm rolls come in two standard sizes: 16mm and 35mm. The images in these rolls can be master copies, duplicates, positives, or negatives. Proper storage of microfilms is a necessity to protect the collection.

What is microfilm used for? Microfilm is comprised of a plastic support (nitrate, acetate, or polyester) with a silver-gelatin emulsion. It is typically unperforated 16mm or 35mm roll film. A larger 105mm was used for the transfer to preservation microfiche, but it is only occasionally found in collections. Microfilm images may be positive or, most often, negative.

What is the difference between microfilm and microfiche? Microfilm is a roll film, and microfiche is a sheet film: either may contain negative or positive images, but negatives are more common. A microcard, like any photo print, is a photosensitive paper card, while a microprint is simply ink printed on a card. An aperture card is a microfilm image or cell mounted in a punch card.

Where can I find information about microfilm & microfiche? For example, in the collection you can find maps, statistical tables, documents, manuscripts, photographs and artworks. In the University of Melbourne Library catalogue microfilm is identified by the prefix MIC/o. Microfiche is identified by the prefix MIC/f. A guide to either a microfilm or microfiche collection is identified by the prefix MIC.

What are the different types of microfilm rolls? Microfilm rolls come in two standard sizes: 16mm and 35mm. The images in these rolls can be master copies, duplicates, positives, or negatives. Proper storage of microfilms is a necessity to protect the collection. If the cellulose nitrate-based film is not stored properly, it will become flammable and pyrophoric.
