

TEMPERATURE RANGE OF HIGH TEMPERATURE ENERGY STORAGE MATERIALS

What is high-temperature energy storage? In high-temperature TES, energy is stored at temperatures ranging from 100°C to above 500°C. High-temperature technologies can be used for short- or long-term storage, similar to low-temperature technologies, and they can also be categorised as sensible, latent and thermochemical storage of heat and cooling (Table 6.4).

What is thermal energy storage? Thermal energy storage is based on either sensible heat storage (SHS), or latent heat storage (LHS) using a phase change material (PCM). Sensible heat storage involves storing energy in the form of heat by changing the internal energy of a material without phase change, and the temperature of the material varies with the amount of heat stored.

What is latent heat thermal energy storage? Latent heat thermal energy storage refers to the storage and recovery of the latent heat during the melting/solidification process of a phase change material (PCM). Among various PCMs, medium- and high-temperature candidates are attractive due to their high energy storage densities and the potentials in achieving high round trip efficiency.

Should a latent thermal energy storage system be integrated? Latent thermal energy storage systems using phase change materials are highly thought for such applications due to their high energy density as compared to their sensible heat counterparts. This review, therefore, gives a summary of major factors that need to be assessed before an integration of the latent thermal energy system is undertaken.

Which material is best suited for thermal energy storage? Recent reviews „, have shown that, in the case of metals, aluminium and its alloys are favoured for thermal energy storage applications. Maximum effectiveness arises when the outlet temperature of the HTF is the same as the phase change temperature.

What is high-temperature heat storage with liquid metals?

High-temperature heat storage with liquid metals can contribute to provide reliable industrial process heat $>500^{\circ}\text{C}$ from renewable (excess) electricity via power-to-heat processes. Liquid metals can also be used to efficiently transport high-temperature waste heat from high-temperature industrial processes to a heat storage medium for later use.
